ABSTRACT

Background: Thalassia hemprichii have reported containing antioxidant effects. However, information on other biological activities relating to the anti-wrinkle properties is limited. The free radical scavenging activity and enzyme inhibitory activity of the plant extracts investigated that they can help restore skin elasticity and thereby slow the wrinkling process. Objective: To evaluate in-vitro antioxidant and anti-collagenase activity of T. hemprichii as a potent ingredient for anti-wrinkle cosmetic. Methods: T. hemprichii was extracted with ethanol 100% (E1) 75% (E2) and ethanol 50% (E3) using maceration extraction method for 24 h, thrice. The extract was examined for total phenolic content, antioxidant activity compared with vitamin C, and the best extract was tested for the inhibitory activity of collagenase. Results: The total phenolic content of T. hemprichii extract was 0,525 ± 0,016 mg GAE/100 g extract (E1) 0,538 ± 0,006 mg GAE/100 g extract (E2) and 0,558 ± 0,090 mg GAE/100 g extract (E3) respectively. The antioxidant activity (% inhibition) of the extract was 38,035 ± 0,252 % (E1), 52,502 ± 6,225 % (E2) and 57,261 ± 0,505 % (E3). Ascorbic acid as a positive control of antioxidant activity showed much higher % inhibition than the sample with 78,055 ± 0,756 %. As the best extract from antioxidant activity, E2 and E3 have inhibited collagenase activity with 51,809 ± 0,164 % and 52,212 ± 0,735 % at 20μg/mL respectively. Conclusion: In general the (T. hemprichii) extract can be used as a potential active ingredient for anti-wrinkles cosmetic. Key words: Thalassia hempricii, Seagrass, Antioxidant, Collagenase, Anti-wrinkle.

INTRODUCTION

Wrinkle, as a manifestation of skin aging, is a natural process that will be experienced by every living creature. But the aging process of each person is not the same, because it is influenced by several factors, both extrinsic and intrinsic. Extrinsic factor such as environmental exposure like sunlight recurring to the skin causing sunburn and dry skin or wrinkle. The intrinsic such as genetics, hormonal changes, metabolic processes factor. Skin repeatedly exposed to ultraviolet light is made up of two type of harmful ray that penetrate deep into the dermis, so cause physical changes and finally generated Reactive Oxigen Scavenger (ROS). ROS cause damage lipid, protein and DNA of the skin. ROS indirectly induce production of MMPs via MAP- kinase pathway. Like all other organs, undergoes chronological aging. In addition, unlike other organs, skin is in direct contact with the environment and therefore undergoes aging as a consequence of environmental damage. The primary environmental factor that causes human skin aging is UV irradiation from the sun. This sun-induced skin aging (photoaging) MMPs are a group of zinc-dependent extracellular proteinases divided into five sub-groups based on their substrate such as collagenase. Collagenase is responsible for extracellular matrix (ECM) cause of collagen breakdown. Elastase is serine proteinase that responsible for the breakdown of elastin in ECM. When collagen and elastin always maintain the skin structural integrity and elasticity, collagen and elastin contribute to undesired wrinkles. Plant extracts usually content phenol, polyphenol, flavonoid they possess antioxidative activity, that used as anti-collagenase and anti-elastase activities. Several studies have reported investigations on plant extracts as inhibitors of proteinases and as anti-oxidants. The anti-ageing and anti-oxidant properties of 23 plant extracts (from 21 plant species) The activity of the potential antioxidants to prevent skin damage cause by ROS. Previous study have revealed that sea grass polyphenols has antioxidant activity. Seagrass also reported has a richer sources of natural antioxidant than seaweeds. Other study reported that Thalassia hempricii, one of Indonesian seagrass species, has IC50 values 123.72 ± 9.99. Nowadays, research on marine plants has been done a lot, to get more information and evidence. However, research on the inhibition of enzymes by sea-
grass is limited. Therefore, this study aims to test the phenolic content, the capacity of antioxidant and inhibitory activity of collagenase enzyme from *Thalassia hemprichii* extract. Inhibition of collagenase activities by natural plant compounds might be a promising approach to prevent extrinsic skin aging like a wrinkle.

**MATERIALS AND METHODS**

**Material**

*Thalassia hemprichii* obtained from Pasauran Beach, Serang, Banten, West Java-Indonesia, 2,2-Diphenyl-1-picrylhydrazyl (DPPH), Gallic acid, Ascorbic acid, C. histolyticum collagenase (ChC) (type IA), N-[3-(2-furyl) acryloyl]-Leu-Gly-Pro-Ala (FALGPA) and Epigallocatechin-echingallate (≥ 95%) were purchased from Sigma-Aldrich. FeCl₃, Folin-Ciocalteu reagent, and Sodium carbonate were purchased from Merck.

**Methods**

**Preparation of seagrass extract**

After collected from Binuangun Beach, Banten, Indonesia. *T. hemprichii* leaves and rhizome were washed immediately using sea water to remove sand particles, and maintained with ice box throughout the expedition. Then *T. hemprichii* rinsed several times, dried and stored. Next, *T. hemprichii* was conducted determination at Biology Center of Indonesian Institute of Sciences (LIPI) to ensure the species.

To get the extract, dried leaves and root were extracted using maceration method for 24 h in 100%, 75% and 50% with ethanol at room temperature under dark condition. Then the mixture was centrifuged (5000 rpm for 10 min) to separate the residue and filtrate. The filtrate was evaporated using a rotary vacuum evaporator (Buchi, Switzerland).

**Phytochemical Screening of Thalassia hemprichii**

Qualitative analysis of the *T. hemprichii* extract determined by Meyer and Dragendorff reagents for alkaloid, ferric chloride test for phenol, magnesium turning test for flavonoids and FeCl₃ for tannins according to previous study.²

**Total Phenolic Content (TPC) of *T. hemprichii* extract**

Total phenols was measured by the modified Folin-Ciocalteu method,⁴ such as treatment of fever, skin diseases, muscle pains, wounds and stomach problems. Hence it is essential to study their bioactive metabolites and medicinal properties when considering their food applications. In the present study, the leaves of six seagrasses Enhalus acoroides, Thalassia hemprichii, Halodule pinifolia, Syringodium isoetifolium, Cymodocea serrulata and Cymodocea rotundata were extracted with aqueous methanol and tested for their antioxidant capacity. Among them, H. pinifolia recorded high phenolic (21.64 mg g⁻¹) and *T. hemprichii* leaves and rhizome were washed immediately using sea water to remove sand particles, and maintained with ice box throughout the expedition. Then *T. hemprichii* rinsed several times, dried and stored. Next, *T. hemprichii* was conducted determination at Biology Center of Indonesian Institute of Sciences (LIPI) to ensure the species.

**Antioxidant activity of *T. hemprichii* extract**

Free radical scavenging activity was determined by Molyneux method,⁸ with slight modifications. As much as 1.0 mL of sample was added to 3.0 mL of 40 ppm DPPH solution. In the dark condition, the mixture was homogenized by vortex for about 20 sec, then kept at room temperature for 30 min, and the absorbance was measured at 517 nm. Ascorbic acid was used as positive control. Antioxidant activity of *T. hemprichii* was expressed as percentage of DPPH scavenging effect (%). The scavenging effect of DPPH radicals was calculated using the equation:

\[
\text{DPPH Scavenging effect(%) } = 1 - \frac{A_s - A_c}{A_o} \times 100
\]

Note: \(A_o\) is the absorbance of the control, \(A_c\) is the absorbance of the sample.

**Anti-Collagenase Activity of *T. hemprichii* extract**

Inhibitory activity of *Thalassia hemprichii* extract against C. histolyticum collagenase (ChC) was measured using spectrophotometry microplate reader by Wittanauer methods.¹¹ with slight modification. 50 ultricine buffer solution (pH 7.5), 50 μl of sample and 50 μl of enzyme (125 Unit/ml ChC, type IA) were added into 96-well microplate. Then 50 μl FALGPA (0.5mM) was added to start the reaction. The solution was then incubated for 15 min. The ChC inhibitory activities of the individual samples were measured by continuously monitoring the decrease in absorbance of FALGPA and expressed as percentage inhibition (%). The relative inhibition was calculated according to Equation below:

\[
\text{Percentage inhibition(%) } = 1 - \frac{O_s}{O_c} \times 100
\]

Note: \(O_c\) is the corrected absorbance enzyme in the presence of samples, \(O_s\) is the corrected absorbance of enzyme without samples.

**RESULTS**

**Phytochemical Screening**

Sample that we used in this study is true *Thalassia hemprichii*, base on determination at The Biology Center of Indonesian Institute of Sciences (LIPI). We found that phytochemical qualitative analysis chemical substances of 100 % (E1), 75 % (E2) and 50 % (E3) ethanolic extract of all parts of the plants (roots and leaves), showed that *T. hemprichii* contained alkaloids, flavonoids, phenols and tannins (Table 1).

**Total Phenolic Content (TPC) of *T. hemprichii* extract**

A calibration curve of Gallic acid (ranging from 100 to 700 μg) was prepared and the total phenolic content was standardized against gallic acid and is expressed as mg Gallic acid equivalents per 100 g of sample on a dry weight basis. R² = 0.9903, y = 0.0007x - 0.0853. Total phenol in extract determined by Meyer and Dragendorff reagents for alkoidal, ferric chloride test for phenol, magnesium turning test for flavonoids and FeCl₃ for tannins according to previous study.²

Anwar, et al. (2018) studied the antioxidant activity and collagenase inhibition of Thalassia hempricii. The study found that the alkaloids under investigation not only demonstrated anti-plasmodial activity but also protected against oxidative stress. Other studies have reported that marine alkaloids can inhibit MMP-1, a human fibroblast collagenase. Flavanoids have been shown to have antioxidant properties because the OH group in flavanoids can donate H atoms in free radicals.

Flavonoids and their metabolites, which are dependent on the arrangement of functional groups about the nuclear structure, have antioxidant activity. Phenolic and flavonoid content is associated with antioxidant activity, especially in terms of DPPH and nitric oxide free radical scavenging. Phenolic compounds have been reported to protect against oxidative stress-mediated disorders and have received intense attention as potential therapeutic agents against a wide range of diseases including neurodegenerative diseases, cancer, diabetes, cardiovascular dysfunction, inflammatory diseases, as well as aging. Phenolic compounds are claimed to be the main active constituent explaining the seagrass antioxidant activity.

Seagrasses are rich in proanthocyanidin (condensed tannin) as one of the phenolic compounds. Phenolic compounds are considered to be the main active constituents explaining the seagrass antioxidant activity. The pharmacological actions of phenolic antioxidants against free radical scavenging are very important in inhibiting wrinkles, as skin which is repeatedly exposed to ultraviolet light every day, can occur wrinkles. Seagrasses may be the cause of antioxidant activity in preventing or inhibiting collagenase activity.

The selection of solvent types is essential for the efficiency of the extraction process, as the compound of solvent with different polarity provides different antioxidant potential. The most widely solvents applied for extraction so far is methanol, ethanol, and acetone or mixtures with water can bring up various polyphenols from various phenolic structures, mainly for quality control purposes. The effects of experimental variables, such as solvent composition and volume and time and temperature on extraction, have been studied. A unique gradient program for the separation of several phenolic classes (hydroquinones, hydroxybenzoic acids, flavan-3-ols, hydroxycinnamic acids, coumarins, flavanones, flavones, tannins or polyphenols) scavenging free radicals with a complex kinetic that involves quick and slow steps of scavenging.

dihydrochalcones and flavonoids. The use of water with other organic solvents as a combination contributes to the formation of fairly small polar media ensuring the extraction of polyphenols. This research choose ethanol-water solvent for making the extract. However, difference state of the seagrass growth site can result difference total content of phenol. For example, TPC for T. hempricii that was collected from Chinnapallam, Gulf of Mannar Biosphere Reserve, Tamilnadu, India has 2.76 ± 0.170 mg GAE/g sample, such as treatment of fever, skin diseases, muscle pains, wounds and stomach problems. Hence it is essential to study their bioactive metabolites and medicinal properties when considering their food applications. In the present study, the leaves of six seagrasses Enhalus acoroides, Thalassia hemprichii, Halodule pinifolia, Syringodium isoetifolium, Cymodocea serrulata and Cymodocea rotundata were extracted with aqueous methanol and tested for their antioxidant capacity. Among them, H. pinifolia recorded high phenolic (21.64 mg g-1). Meanwhile, T. hempricii that was collected from Palk bay, India has 6 mg GAE/g sample. Environmental conditions have great influences in the antioxidant property and the accumulation of the phytochemicals. The DPPH assay has been commonly used to measure the free radical-scavenging ability of plants. The antioxidant effect on DPPH radical scavenging may be due to those ability to donate hydrogen. When the DPPH solution is mixed with a substrate acting as a hydrogen atom donor, a stable non-radical DPPH formed characterized by a simultaneous change of violet color to pale yellow. DPPH assay is most suitable for polar compounds because the DPPH crystals can dissolve easily in a commonly solvent and give maximum absorbance. Based on Figure 2, E2 and E3 shows greater % scavenging effect, compared to E1. TPC of T. hempricii related with the antioxidant activity. Other research reported 38.62 ± 0.62 % for inhibitory activity of DPPH assay of T. hempricii. Such as treatment of fever, skin diseases, muscle pains, wounds and stomach problems. Hence it is essential to study their bioactive metabolites and medicinal properties when considering their food applications. In the present study, the leaves of six seagrasses Enhalus acoroides, Thalassia hemprichii, Halodule pinifolia, Syringodium isoetifolium, Cymodocea serrulata and Cymodocea rotundata were extracted with aqueous methanol and tested for their antioxidant capacity. Among them, H. pinifolia recorded high phenolic (21.64 mg g-1). The collagenase inhibition by E3 related with the total phenolic content and antioxidant activity of DPPH. Additionally, Antioxidant activities of plants extracts were correlated with their total phenolic content. The characteristics of polyphenols may differ, depend on the solvent used during the extraction of the two solvents. There’s can be different mechanism of anti-aging or anti-wrinkle properties on plants extract. So, E3 might be used as an active ingredient for anti-aging or anti-wrinkle products.

CONCLUSION

In general, the T. hempricii extract can be used as a potential active ingredient for anti-wrinkles cosmetic.
